Journal Subject Code: [132] Arrhythmias - basic studies
Abstract:

**Background** - Hypothermia has been reported to induce ventricular tachycardia and fibrillation (VT/VF) in patients with early repolarization (ER) pattern. This study examines the cellular mechanisms underlying VT/VF associated with hypothermia in an experimental model of ER syndrome (ERS) and examines the effectiveness of quinidine, cilostazol and milrinone to prevent hypothermia-induced arrhythmias.

**Method and Results** - Transmembrane action potentials (AP) were simultaneously recorded from 2 epicardial and 1 endocardial site of coronary-perfused canine left-ventricular wedge preparations, together with a pseudo-ECG. A combination of NS5806 (3-10 μM) and verapamil (1μM) was used to pharmacologically model the genetic mutations responsible for ERS. Acetylcholine (3μM) was used to simulate increased parasympathetic tone, which is known to promote ER. In control, lowering the temperature of the coronary perfusate to induce mild hypothermia (32°C-34°C) resulted in increased J wave area on the ECG and accentuated epicardial AP notch but no arrhythmic activity. In the setting of ER, hypothermia caused further accentuation of the epicardial AP notch, leading to loss of the AP dome at some sites but not others, thus creating the substrate for development of phase-2-reentry and VT/VF. Addition of the I_{to} antagonist quinidine (5 μM) or the phosphodiesterase III inhibitors cilostazol (10 μM) or milrinone (5 μM), diminished the ER manifestations and prevented the hypothermia-induced phase 2 reentry and VT/VF.

**Conclusions** - Hypothermia leads to VT/VF in the setting of ER by exaggerating repolarization abnormalities, leading to development of phase-2-reentry. Quinidine, cilostazol and milrinone suppress the hypothermia-induced VT/VF by reversing the repolarization abnormalities.

**Key words:** ventricular tachycardia, ventricular fibrillation, phosphodiesterase inhibitor, J wave syndrome, early repolarization syndrome
Introduction

An early repolarization (ER) pattern in the ECG is characterized by a J-point elevation with or without ST-segment elevation as well as notching or slurring of the terminal part of the QRS complex. ER is a relatively common ECG finding, long considered to be benign. Recent studies point to an association of ER with the development of ventricular tachycardia (VT) and fibrillation (VF) leading to sudden cardiac death. \(^1\)\(^-\)\(^4\) Early repolarization has been divided into three subtypes. Type 1 involves an ER pattern localized to the lateral leads. In Type 2 the ER pattern is present in the inferior and infero-lateral leads, and in Type 3 it is present globally in the inferior, lateral and anterior or right precordial leads. Individuals with Type 1 rarely develop VT/VF. Type 2 is associated with a higher level of risk and individuals displaying a Type 3 ER have the highest risk for developing life-threatening arrhythmias, including electrical storms. \(^4\)

Hypothermia is known to contribute to the development of prominent J waves leading to VT/VF. \(^4\)\(^-\)\(^6\) Current guidelines recommend mild therapeutic hypothermia (TH) to prevent neurological damage following a cardiac arrest. \(^7\)\(^-\)\(^8\) The extent to which hypothermia contributes to arrhythmogenesis and the mechanisms involved are not well defined. Recent reports point to an association between ER and the development of VT/VF in the setting of hypothermia. \(^9\)\(^,\)\(^10\) The present study was designed to test the hypothesis that ER, by causing outward shift in the balance of currents active during the early phases of the epicardial action potential (AP), exacerbates the response to hypothermia, thus leading to prominent J waves, phase 2 reentry and VT/VF. In addition, we examine the hypothesis that pharmacologic agents capable of producing an inward shift in the balance of current in the early phases of the epicardial AP, either by inhibiting transient outward current (I\(_{\text{to}}\)) (quinidine) or augmenting I\(_{\text{Ca}}\) (cilostazol and milrinone), can protect against hypothermia-induced VT/VF in the setting of ER.
Methods

Arterially Perfused Wedge of Canine Left Ventricle

We employed floating glass microelectrode techniques to simultaneously record APs from 2 epicardial (Epi) and 1 endocardial (Endo) site in coronary-perfused wedge preparations isolated from the inferior and lateral regions of the canine left ventricle (LV), together with pseudo-ECG recorded across the bath along the Endo-Epi axis. Detailed methods are provided in the online supplement. The Tyrode’s solution was warmed while passing through the heated coils to deliver the perfusate at 37°C. To simulate hypothermia, the solution was redirected to two coiled-perfusion lines in series immersed in beakers filled with water, before reaching the tissues. We lowered the temperature of the perfusate to 32°C.

Measurements of Action Potential Parameters

The Epi AP notch magnitude (NM) [phase 1 magnitude / phase 0 amplitude x 100], phase 0 to phase 2 interval; [time between the first 2 peaks of the derivative of the AP] as well as the notch index (NI); [NM × (Ph 0 to Ph 2 interval)] which approximates the area of the notch, were measured in AP recordings as previously described (Figure 1).11

J Wave Area Calculations

The area of the J wave was calculated as follows: The start of J-wave was defined using derivative of the ECG signal. In case of clear separation it was set at the time when this derivative is zero which corresponds to the notch between R wave and J wave. When this separation was not clearly visible, this time was set at the moment when the negative derivative attains its maximal value (i.e. minimal rate of decline) after the maximal downslope of the R wave. The J wave area was expressed as mV x ms (Figure 1).
Statistical Analysis

Results are presented as mean ± S.E.M. (standard error of the mean) throughout the manuscript. Statistical comparisons were made using Student’s t-test for Table 1 A-B. One way repeated measures analysis of variance were used for Table 1 C-E.; followed by pairwise comparisons corrected by Bonferroni method.

Results

Effects of Hypothermia in Left Ventricular Wedge Preparation

In an initial series of 7 experiments, we examined the effects of hypothermia in coronary-perfused caninc LV wedge preparations. Lowering the temperature to 32-34°C caused prolongation of AP durations (APDs) and accentuation of the AP notch in the epicardium but not endocardium, thus augmenting the amplitude of the J wave (Figure 2, Table 1A). Under baseline condition, lowering the temperature to 32°C failed to cause loss of the Epi AP dome or to induce arrhythmic activities.

Effects of Hypothermia in ER-Induced Left Ventricular Wedge Preparation

Because vagal influences are known to accentuate the electrocardiographic and arrhythmic manifestations of ER,12-14 in a second series of experiments, we induced an early repolarization phenotype using a combination of the I_{so} activator NS5806 (3-10 μM), the Ca^{2+} channel blocker verapamil (1 μM) and acetylcholine (ACh) (3 μM) added to the coronary perfusate. The combination accentuated the AP notch in epicardium but not endocardium, thus leading to augmentation of the electrocardiographic J wave but no arrhythmia (Figure 3A). Hypothermia caused a further increase of J wave area, NM and notch index, leading to all-or-none repolarization at the end of phase 1 of the Epi AP. Loss of the Epi AP dome at some sites but not others resulted in a prominent increase in epicardial dispersion of repolarization (EDR) and
transmural dispersion of repolarization (TDR). The voltage gradient between the abbreviated Epi AP and the relatively normal Endo AP produced a prominent ST segment elevation. A prominent APD gradient developed between sites displaying a normal AP dome and adjacent sites where the dome was lost, thus creating a vulnerable window within epicardium as well as between epicardium and endocardium across the ventricular wall. Propagation of the dome from regions at which it was maintained to regions, at which it was lost, caused local re-excitation via a phase 2 reentry mechanism, leading to the development of closely coupled extrasystoles and polymorphic VT/VF (Figure 3).

Similar results were obtained in 12 experiments. Composite of the action potential and electrocardiographic parameters are presented in Figure 3 and Table 1B.

**Effect of Quinidine, Cilostazol and Milrinone to Suppress and Prevent Hypothermia-Induced Arrhythmogenesis**

Quinidine has been shown to restore transmural electrical homogeneity and abort arrhythmic activity in the J wave syndromes. In another series of 5 experiments we tested the hypothesis that quinidine could prevent the hypothermia-induced VT/VF developing in the setting of ER owing to its effect to reduce the I_{to}. Ventricular tachycardia/ventricular fibrillation was first induced by exposure of the LV wedge to hypothermia + NS 5806 (3-10 μM) + verapamil (1μM) + ACh (3 μM). Temperature was then restored to 37°C, at which point the arrhythmia subsided. Quinidine (5 μM) was then added to the coronary perfusate and hypothermia was re-induced. Quinidine (5 μM) diminished the AP notch and J wave at 37°C and prevented loss of the Epi AP dome and development of the repolarization abnormalities, thus preventing the development of phase 2 reentry and VT/VF when temperature was reduced to 32°C (Figure 4). A similar effect of quinidine to prevent VT/VF was observed in 5 out of 5 preparations exposed to hypothermia
In 2 experiments, quinidine (5-10 μM) was added during the VT/VF episode at 32°C. In both cases the drug suppressed all arrhythmic activity and restored electrical homogeneity throughout the preparation.

In a final series of experiments, we examined the effectiveness of the phosphodiesterase III inhibitors cilostazol and milrinone to prevent hypothermia-induced VT/VF in the setting of ER. These agents are known to augment I_{Ca} via their action to increase cAMP. Here again, we first demonstrated the ability of the combination of provocative agents and hypothermia (32°C) to accentuate ER, thus creating a large epicardial and transmural dispersion of repolarization giving rise to phase 2 reentry and VT/VF. We then restored temperature to 37°C, which reversed the repolarization abnormality and suppressed VT/VF. The addition of cilostazol (10 μM) or milrinone (5 μM) reduced the Epi AP notch at 37°C and prevented the repolarization abnormality as well as the development of phase 2 reentry and VT/VF when temperature was once again reduced to 32°C (Figures 5 and 6). Both agents prevented the hypothermia-induced increase in TDR, EDR; Epi AP notch magnitude, notch index, and J wave area on pseudo ECG. Cilostazol was successful in preventing the VT/VF in 5 out of 7 preparations. Similarly, milrinone (5 μM) prevented the hypothermia-induced VT/VF in 5 out of 7 preparations (Figures 5 and 6, Table 1D and E).

Discussion

Therapeutic hypothermia is today widely used to prevent tissue injury secondary to cardiac arrest, ischemic stroke, traumatic brain and spinal cord injury, and neurogenic fever following brain trauma. Subjects are generally cooled to a target temperature of 32–34°C (90–93°F). In cases of cardiac arrest, Holzer et al. reported that 55% of 137 patients in the hypothermia group experienced favorable outcomes, compared with only 39% in the group that
received standard care following resuscitation. Among the adverse events encountered with TH is the development of cardiac arrhythmias. Hypothermia’s adverse events increase in severity the lower a patient’s body temperature is reduced. The accepted medical standard is to not drop below 32°C (90°F).

The factors that predispose to hypothermia-induced arrhythmogenesis and the mechanisms involved are poorly understood. Recent studies report an association between ER and the development of hypothermia-induced VT/VF. The present study recapitulates this clinical phenomenon in an experimental model consisting of the canine LV coronary-perfused LV wedge preparation, provides a mechanistic understanding of the cellular basis for the development of VT/VF in the setting of ER and hypothermia, and identifies potential therapeutic agents that may be useful in suppressing or preventing the development of hypothermia-induced VT/VF.

**Mechanism of Hypothermia-Induced arrhythmias in Patients with Early Repolarization Syndrome**

The J wave syndrome, which includes both Brugada and early repolarization (ERS) syndromes, has been associated with genetic defects that cause a gain of function of I_{to} and a loss of function of I_{Ca} among many others. Both syndromes are also known to be aggravated by increased vagal tone. In this study, we pharmacologically mimicked these genetic and autonomic factors to create ER using the I_{to} agonist NS5806 (3-10 µM), I_{Ca} antagonist verapamil (1 µM) and acetylcholine (3 µM). ACh contributes to the generation of the ERS phenotype by causing both indirect (via accentuated antagonism) and direct use-dependent inhibition of I_{Ca}. Litovsky and Antzelevitch demonstrated in 1990 the ability of ACh to accentuate the epicardial AP notch and to cause loss of AP dome.
Under baseline conditions, lowering temperature to 32°C caused the appearance of prominent J wave in the ECG due to accentuation of the Epi AP notch. In the absence of provocative agents designed to generate an ER pattern in the ECG, no arrhythmic activity was observed in any of the preparations. Following the generation of the ER phenotype, relatively mild hypothermia (32°C to 34°C) caused all-or-none repolarization, leading to loss of the AP dome at some epicardial sites but not others. This resulted in dispersion of AP repolarization both within epicardium and between epicardium and endocardium. Propagation of the AP dome, from sites at which the dome was maintained to sites at which it was lost, caused local reexcitation via a phase 2 re-entry mechanism, leading to the development of closely coupled extrasystoles and VT/VF.

Consistent with these observations is the demonstration by Nishida and co-workers that vagal nerve stimulation accentuates the hypothermia–induced spike and dome AP morphology in canine epicardium. Hypothermia is thought to accentuate the AP notch due to the difference in the Q10 for activation of I\textsubscript{to} and I\textsubscript{Ca}. The greater slowing of I\textsubscript{Ca} activation leaves I\textsubscript{to} less opposed, thus accentuating phase 1 repolarization and the AP notch. Thus an effective strategy to reduce the impact of hypothermia would be to either reduce I\textsubscript{to} or augment I\textsubscript{Ca}, thus producing an inward shift in the balance of current during the early phase of the AP. In three experimental series we tested this hypothesis by pretreating the preparations with either quinidine to block I\textsubscript{to} or cilostazol and milrinone to augment I\textsubscript{Ca}.

**Potential Therapeutic Interventions**

In support of our hypothesis, quinidine (5 μM) proved capable of both suppressing and preventing the hypothermia-induced VT/VF in all preparations in which the drug was tested.
Cilostazol (10 μM) and milrinone (5 μM) were effective in preventing the hypothermia-induced VT/VF in most but not all preparations. These agents increase I_{Ca} secondary to an increase in cAMP. It is noteworthy that cilostazol was reported to be able to prevent VT/VF in a patient with ERS over an extended period of time.\textsuperscript{21} A beneficial effect of milrinone has as yet not been reported.

**Conclusion**

The present study demonstrates the effect of hypothermia to accentuate repolarization abnormalities within the left ventricular epicardium and that in the setting of ER, this effect of hypothermia is accentuated leading to the development of phase 2 reentry and VT/VF. We also provide support for the hypothesis that agents capable of producing an inward shift in the balance of current during the early phases of the AP can exert a protective and/or ameliorative effect. Quinidine by virtue of its I_{Na} inhibition and cilostazol and milrinone, by virtue of their effects to augment I_{Ca}, are effective in partially reversing the hypothermia-induced repolarization abnormalities, thus restoring electrical homogeneity and abolishing the arrhythmogenic substrate.

**Study Limitations**

As with all data derived from experimental animal models, extrapolation of the data from *in vitro* models to the clinic must be done with great care.

**Figure 3.** Arrhythmogenic effect of hypothermia in the setting of early repolarization (ER). A. All panels show traces recorded at 2 epicardial (Epi) and 1 endocardial (Endo) sites, together with a pseudo ECG. A. The first grouping was recorded 30 min after addition of NS5806 (10 μM), verapamil (1 μM) and acetylcholine (ACh) (3 μM) to the coronary perfusate at 37°C. The second grouping was recorded 10 min after lowering of the perfusate to 32°C; hypothermia in the setting of ER leads to the development of phase 2 reentry and polymorphic ventricular
tachycardia. **B-F.** Composite data showing the effect of lowering coronary perfusate temperature to 32°C on action potential duration at 90% repolarization (APD90), notch magnitude, notch index and J wave area. EDR = epicardial dispersion of repolarization; TDR = transmural dispersion of repolarization. All recordings were obtained at a basic cycle length of 1000 ms. Results are mean ± S.E.M. *p<0.05, †p<0.01 vs. NS 5806 + Verapamil + ACh combination. n=5 for B, C, D, E and F.

**Figure 4.** Quinidine prevents hypothermia-induced ventricular tachycardia and fibrillation (VT/VF) in the setting of early repolarization. **A.** The first grouping shows recordings from 2 epicardial (Epi) and 1 endocardial (Endo) sites, together with a pseudo-ECG after exposure of the left ventricular wedge to NS 5806 (3-10 μM) + verapamil (1μM) + acetylcholine (ACh) (3 μM). In the second grouping, the coronary perfusate temperature was lowered to 32°C, leading to development of VT/VF. Temperature was then restored to 37°C, at which point the arrhythmia subsided (not shown). The third grouping was recorded after addition of quinidine (5 μM) and re-induction of hypothermia. Quinidine (5 μM) diminished the action potential (AP) notch and J wave at 37°C and prevented loss of the Epi AP dome and development of the repolarization abnormalities, thus preventing the development of phase 2 reentry and VT/VF when temperature was reduced to 32°C. **B-F.** Composite data showing the effect of lowering coronary perfusate temperature to 32°C on AP duration at 90% repolarization (APD90), notch magnitude, notch index and J wave area in the presence and absence of quinidine. All recordings were obtained at a basic cycle length of 1000 ms. EDR = epicardial dispersion of repolarization; TDR = transmural dispersion of repolarization. Results are mean ± S.E.M. *p<0.05, †p<0.01 vs. NS 5806 + Verapamil + ACh combination. n=5 for B, C, D, E and F.
Figure 5. Cilostazol prevents hypothermia-induced ventricular tachycardia and ventricular fibrillation (VT/VF) in the setting of early repolarization. A. The first grouping shows recordings from 2 epicardial (Epi) and 1 endocardial (Endo) sites, together with a pseudo-ECG after exposure of the left ventricular wedge to NS 5806 (3-10 μM) + verapamil (1μM) + acetylcholine (ACh) (3 μM). In the second grouping, the coronary perfusate temperature was lowered to 32°C, leading to development of VT/VF. Temperature was then restored to 37°C, at which point the arrhythmia subsided (not shown). The third grouping was recorded after addition of cilostazol (10 μM) and re-induction of hypothermia. Cilostazol (10 μM) diminished the action potential (AP) notch and J wave at 37°C and prevented loss of the Epi AP dome and development of the repolarization abnormalities, thus preventing the development of phase 2 reentry and VT/VF in 5 of 7 preparations when temperature was reduced to 32°C. B-F. Composite data showing the effect of lowering coronary perfusate temperature to 32°C on AP duration at 90% repolarization (APD₉₀), notch magnitude, notch index and J wave area in the presence and absence of cilostazol. EDR = epicardial dispersion of repolarization; TDR = transmural dispersion of repolarization. All recordings were obtained at a basic cycle length of 1000 ms. Results are mean ± S.E.M. *p<0.05, †p<0.01 vs. NS 5806 + Verapamil + ACh combination. n=5 for B, C, D, E and F.

Figure 6. Milrinone prevents hypothermia-induced ventricular tachycardia and fibrillation (VT/VF) in the setting of early repolarization. A. The first grouping shows recordings from 2 epicardial (Epi) and 1 endocardial (Endo) sites, together with a pseudo-ECG after exposure of the left ventricular wedge to NS 5806 (3-10 μM) + verapamil (1μM) + Acetylcholine (ACh) (3 μM). The coronary perfusate temperature was lowered to 32°C, leading to development of
VT/VF. Temperature was then restored to 37°C, at which point the arrhythmia subsided (not shown). The third grouping was recorded after addition of milrinone (5 μM) and re-induction of hypothermia. Milrinone (5 μM) diminished the action potential (AP) notch and J wave at 37°C and prevented loss of the Epi AP dome and development of the repolarization abnormalities, thus preventing the development of phase 2 reentry and VT/VF in 5 or 7 preparations when temperature was reduced to 32°C. B-E. Composite data showing the effect of lowering coronary perfusate temperature to 32°C on AP duration at 90% repolarization (APD$_{90}$), notch magnitude, notch index and J wave area in the presence and absence of milrinone. EDR = epicardial dispersion of repolarization; TDR = transmural dispersion of repolarization. All recordings were obtained at a basic cycle length of 1000 ms. Results are mean ± S.E.M. *p<0.05, †p<0.01 vs. NS 5806 + Verapamil + ACh combination. n=5 for B, C, D, E and F.
Cellular Mechanism Underlying Hypothermia-Induced VT/VF in the Setting of Early Repolarization and the Protective Effect of Quinidine, Cilostazol and Milrinone

SUPPLEMENTAL MATERIAL

Methods

All experiments were carried out in compliance with the Guide for Care and Use of Laboratory Animals published by the National Institutes of Health (NIH publication No 85-23, Revised 1996) and approved by the Institutional Animal Care and Use Committee. We used mongrel dogs weighing 20–35 kg of either sex. The chest was opened via a left thoracotomy and the heart was excised. Transmural wedge preparations with dimensions of up to 32 x 20 x 15 mm were dissected from the LV wall. The preparations were cannulated via a distal diagonal branch of the left anterior descending coronary artery, or a left marginal branch of the circumflex artery, or a branch of the posterior descending artery and perfused with cardioplegic solution (Tyrode’s containing 12 mmol/L KCl). Non-perfused regions of the tissue were removed using a razor blade. The preparations were then placed in a tissue bath and perfused with oxygenated Tyrode’s solution (mM): NaCl 129, KCl 4, NaH₂PO₄ 0.9, NaHCO₃ 20, CaCl₂ 1.8, MgSO₄ 0.5, glucose 5.5, pH 7.4. The perfusate was delivered using a peristaltic pump (Masterflex peristaltic pump, Cole Parmer Instrument Co, Niles, Illinois) at a constant flow rate at 12-14 mL/min warmed to 37±0.5°C.

The preparations were equilibrated in the tissue bath until electrically stable, usually 1 hour. Pacing stimuli were delivered to the endocardial surface basic cycle length of 1000 ms using bipolar silver electrodes insulated except at the tips. The temperature of the perfusate was controlled by a heating bath associated with a glass condenser, a tube internally coiled within a wide cylindrical housing. The Tyrode’s solution was warmed while passing through the heated coils to deliver the perfusate at 37°C. To simulate hypothermia, the solution was redirected to
two coiled-perfusion lines in series immersed in beakers filled with water, before reaching the tissues. We lowered the temperature of the perfusate to 32°C.

A transmural ECG was recorded using two electrodes consisting of AgCl half cells placed in the tissue bath, 1.0 to 1.5 cm from the Epi and Endo surfaces of the preparation, along the same axis as the transmembrane recordings (Epi electrode is connected to the positive input of the ECG amplifier). Transmembrane APs were simultaneously recorded from two Epi sites (Epi 1 and Epi 2; Epi1-Epi2 distance was approx. 10-20 mm) and one Endo site with the use of floating microelectrodes (DC resistance=10 to 20 MΩ) filled with 2.7 mol/L KCl, each connected to a high-input impedance amplifier. Impalements were obtained from the Epi and Endo surfaces of the preparation at positions approximating the transmural axis of the ECG recording. Spike 2 for Windows (Cambridge Electronic Design, Cambridge, UK) was used to record and analyze the ECG and the AP. NS 5806, cilostazol and milrinone were dissolved in dimethyl sulphoxide (DMSO); acetylcholine, verapamil HCl, quinidine, were dissolved in distilled water (10 mM stock). DMSO controls were performed to ensure the absence of an effect of the solvent.
